Health Effects of Aviation Ultrafine and Ultra-Ultrafine Particles Technical Report

Introduction & Scope

This technical report summarizes the current state of the science regarding the potential for adverse health effects from exposure to ultrafine particles (UFPs), commonly considered by the scientific community to be particulate matter (PM) with an aerodynamic diameter of 100 nanometers (nm), or 0.1 micrometers (µm), or less. Ultra-ultrafine particles (UUFPs) are a relatively newly measured subset of UFPs, commonly considered to have aerodynamic diameters of less than 20 nm, or 0.020 µm (Austin et al. 2021). There are limited familiar touchstones to contextualize how small UFPs and UUFPs are; for example, a single human hair is more than 1,000 times wider than even the largest UFPs.

Exposure to UFP and UUFP emissions generated by the combustion of jet fuel during aircraft operations, including arrival, descent, landing, taxi-in, taxi-out, takeoff, climb-out, and departure ascent (collectively, "aviation activity"), is examined. Although the Port of Seattle lacks the legal authority to address or mitigate effects from aircraft emissions under Clean Air Act (CAA) section 233, 42 U.S. Code § 7573, it has prepared this technical report as part of its separate disclosure obligations under the Washington State Environmental Policy Act (SEPA) and as part of its SEPA Environmental Impact Statement (EIS), which evaluates the effects of the Near-Term Projects (NTPs) associated with the Seattle-Tacoma International Airport (SEA) Sustainable Airport Master Plan (SAMP).

These UFPs and UUFPs are subsets of broader classifications of PM, including PM with an aerodynamic diameter of 2.5 µm or less ($PM_{2.5}$). Regulatory standards have been established by the U.S. Environmental Protection Agency (EPA) for $PM_{2.5}$. These standards are designed to be protective of public health and welfare from exposure to $PM_{2.5}$. For regulatory standards for UFPs or UUFPs to be considered, the scientific consensus would need to demonstrate specific causal health effects from UFP and UUFP exposures that are distinct and independent from the broader health effects currently addressed by $PM_{2.5}$ standards. The current state of the science has not matured to a point that would support the adoption of regulatory standards for UFPs or UUFPs.

EPA has not proposed or adopted thresholds or policies related to the emission of UFPs. Similarly, neither EPA nor other applicable authorities have established guidance or recommendations for evaluating the isolated health effects of UFP exposure. The most comprehensive reviews to date—including the EPA's 2019/2022 Integrated Science Assessment (ISA) and Bergmann et al.'s 2026 literature meta-analysis—classify the evidence as "suggestive of, but not sufficient to infer, a causal relationship" or "inadequate to infer" causality. While evidence has established a causal relationship between $PM_{2.5}$ and health effects sufficient to warrant regulatory action, the same is not true of UFPs or UUFPs.

Particle Characterization

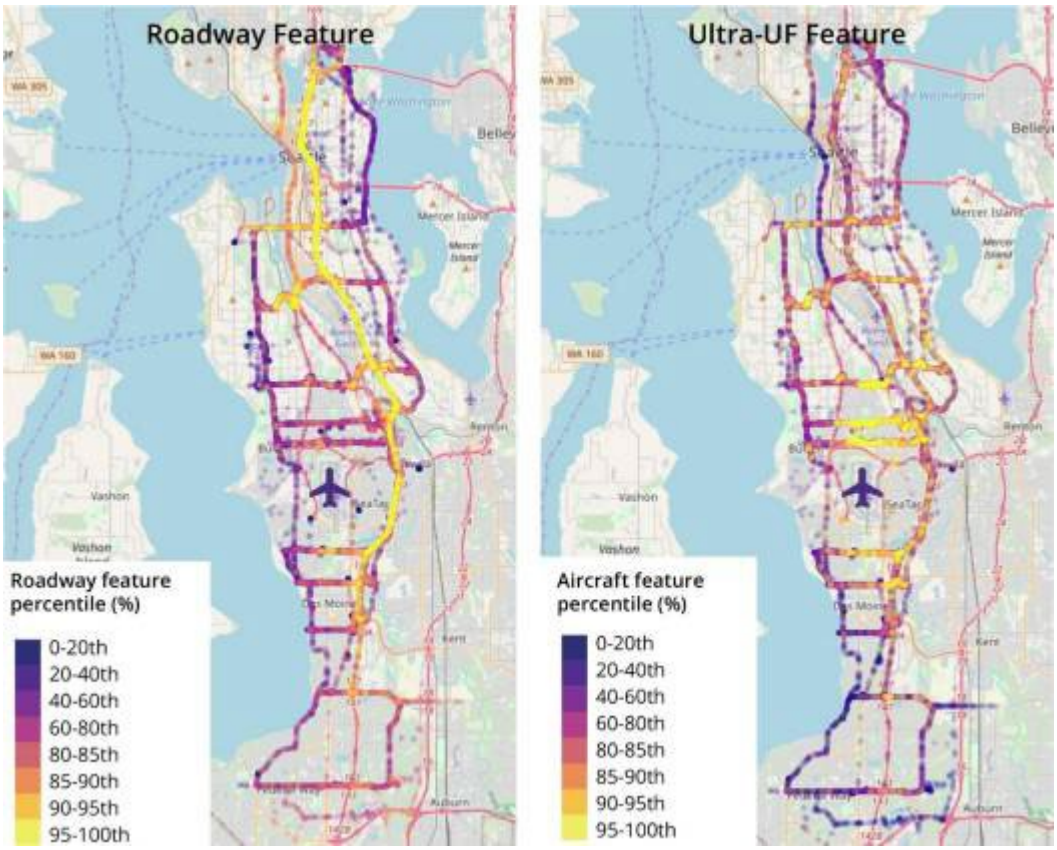
To support understanding of the state of the science, this section discusses the characteristics of UFP and UUFP emissions and UFP apportionment across sources; spatial gradients and particle number concentrations (PNC); and temporal patterns tied to flight modes.

Black carbon (BC) represents the non-volatile, solid carbonaceous core of many aircraft-emitted UFPs. Formed during incomplete combustion of fuel, BC particles from aviation activity are initially generated in the UUFP size range and dominate near-field PNC. BC UFPs are formed by the combustion of fuels, including from diesel highway vehicles ubiquitous to the urban environment.

The University of Washington's Mobile ObserVations of Ultrafine Particles (MOV-UP) study (2019) at SEA suggested that aircraft operations generate a broad and detectable footprint of UFPs in surrounding communities. The research employed mobile monitoring platforms to sample air quality along transects extending up to 10 miles north and south of the airport, perpendicular to flight paths, and covered four seasons, capturing both north and south runway flows. The study found that total UFP (10 to 1,000 nm) PNC was elevated beneath aircraft flight paths but was highest on Interstate 5 (I-5), indicating that total PNC alone could not distinguish between aircraft and roadway source particles. Levels of BC were also highest on highways, further emphasizing that multiple sources, not only aircraft, contribute to urban UFP and UUFP exposure (Austin et al. 2021).

Principal Component Analysis (PCA) identified two separate features in the SEA data: an "Ultra-UF" feature, strongly correlated with particles in the 10 to 36 nm range and associated with aircraft emissions, and a "Roadway" feature, correlated with particles 20 to 36 nm and linked to BC and vehicle emissions. Spatial mapping revealed that the aircraft-related PNCs were elevated on highways but peaked directly beneath landing paths and shifted with runway direction, while the roadway feature showed a strong gradient around major highways independent of airport operations. **Figure 1**, excerpted from Austin et al.'s study (2021), illustrates this gradient in the vicinity of SEA. The study also found that landing-mode aircraft activity produced greater UFP emissions than takeoff-mode activity (Austin et al. 2021).

A comparable study at Los Angeles International Airport (LAX) reflects similar observations to the MOV-UP study, demonstrating that aircraft engines emit large numbers of UFPs forming persistent plumes extending up to 16 kilometers (km) (10 miles) downwind, with localized peaks up to ten times background levels. The spatial pattern of UFPs from aviation activity at LAX aligned with prevailing winds and flight trajectories, showing consistent impacts year-round and minimal upwind influence (Austin et al. 2011; Hudda et al. 2014).



Source: Austin et al. 2021
Notes: Percentiles range from 0th percentile representing the smallest observed value to 100th representing the largest observed value.
Figure 1. Spatial distribution of the "Ultra-UF" and "roadway" features.

Additional studies at other major airports, including at LAX, Hartsfield-Jackson Atlanta International Airport (ATL), and Logan International Airport (BOS) further reinforce these spatial findings, with peak aviation-related PNCs strongly associated with aircraft approach paths, 3-to-5 fold increases in PNCs at distances of 5 to 10 km (3.1 to 6.2 miles) from the airport relative to background, and aviation-related UUFPs community exposure being generally lower than that of roadway-related BC UUFP (17–26 percent of community exposure from aviation sources) (Mueller et al. 2025; Riley et al. 2016; Wang et al. 2024; Zhang et al. 2020).

The overall state of science of particulate characterization has matured significantly since foundational studies, such as the 2003 source apportionment study at LAX, first characterized and apportioned UFP PNCs associated with aviation-related sources from those of broader urban backgrounds and roadway sources (Westerdahl et al. 2008). However, the value of further studies is limited by the more nascent state of independent UFP health effect causality and exposure science.

Health Effects of Ultrafine Particles and Ultra-Ultrafine Particles

Interpreting the health effects discussed in the UFP literature requires an understanding of the methods by which causality—the relationship between exposure to a pollutant and the development of symptoms from that exposure—is characterized. This characterization is based on the consistency of effects, coherence between real-world and experimental results, biological plausibility from the available studies, risk of bias, and other contributing factors (EPA 2019).

Evidence classifications typically used in EPA's ISA, by the U.S. National Institute of Environmental Health Services' Health Assessment and Translation (HAT) group, and used across literature sources include:

- Causal relationship – Evidence is sufficient to conclude that a cause-and-effect relationship exists between exposure and the health outcome, supported by consistent findings across multiple study designs and strong biological plausibility.
- Likely to be a causal relationship – Evidence generally supports a causal interpretation, but critical uncertainties remain, such as limitations in exposure assessment, or a smaller body of supporting studies.
- Suggestive of a causal relationship (or suggestive association) – Evidence suggests an association between exposure and the health outcome, but is limited by inconsistency, limited studies, or methodological constraints that preclude causal conclusions.
- Inadequate to infer a causal relationship (inconclusive) – Available evidence is insufficient in quantity, quality, or consistency to determine whether a causal relationship exists.
- Not likely to be a causal relationship – Evidence suggests that a causal relationship is unlikely, often based on consistent null findings across well-conducted studies.

Within these or other frameworks applicable to the evaluation of health evidence, classifications such as "likely causal" or "suggestive" do not establish definitive cause-and-effect relationships and do not, on their own, attribute specific exposure-related hazards. Instead, in the case of UFPs and UUFPs, these findings generally suggest a need for further research, such as to distinguish the attributable health effects of UFP from those of collective $PM_{2.5}$ or from other co-pollutants (Bergmann et al. 2026).

Cardiovascular

Key Finding: Current research has not established a causal connection between short-term UFP exposure and cardiovascular disease; the evidence across short- and long-term studies is best characterized as inconclusive to suggestive.

Cardiovascular health effects are among the more frequently evaluated health endpoints in available UFP research. Research has shown that UFPs can cross biological transport barriers in the lungs and enter into cardiovascular circulation (Kwon et al. 2020).

Short-term exposure studies near airports and roadways have evaluated high- and low-frequency power—a metric reflecting heart-rate variability across frequency ranges which can be indicative of adverse cardiovascular stress—and drawn a suggestive association of stress to UFP exposure that is greater than that of $PM_{2.5}$ alone (Wang et al. 2024). The broader base of evidence, however, remains inconsistent; of six other studies considering UFP association to cardiovascular mortality, three reported positive associations, two showed no effect, and one reported an inverse association (Ohlwein et al. 2019). A review of cardiovascular-related healthcare utilization from populations exposed to aviation-related UFPs showed a weak positive association which, after the effects of co-pollutants were considered, attenuated to inconclusive independent UFP-specific influence (Ohlwein et al. 2019). A 2013 review from the Health Effects Institute (HEI) similarly identified inconsistent or inconclusive evidence across 15 studies for cardiovascular effects from UFPs (Health Effects Institute 2013).

Long-term epidemiological studies are limited with respect to cardiovascular UFP health effects. The Bergmann et al. (2026) systematic review covered a limited number of long-term studies which evaluated cardiovascular effects and found inconsistent cardiovascular health effects with generally wide confidence intervals. While some cardiovascular associations were observed in single-pollutant models, most attenuated to inconclusive after adjustment for $PM_{2.5}$ or other co-pollutants.

Respiratory

Key Finding: The evidence has not established a causal connection between UFP exposure and adverse respiratory outcomes; some suggestive associations have been proposed for short-term inflammatory responses, but long-term effects remain inconclusive.

Exacerbation of asthma, reduction in lung function, airway inflammation, chronic obstructive pulmonary disease (COPD) progression, lung cancer, and respiratory mortality are commonly hypothesized outcomes of UFP exposure. The biological plausibility of respiratory effects is well understood, with studies indicating aviation-related UFP lung deposition fractions increased to 0.7-0.8, up from 0.5-0.7 under an urban background, due to the smaller size of aviation-related UFPs (Hudda, N. and Fruin, S.A. 2016).

Four of five studies addressing respiratory mortality health effects of UFPs synthesized in Ohlwein et al.'s review (2019) estimated positive but statistically nonsignificant associations, and did not find smaller UFP size fractions, such as those associated with aviation, to be consistently associated with respiratory mortality. Similar to the studies on cardiovascular effects, studies that isolate respiratory UFP effects from those of co-pollutants like nitrogen oxides, PM_{10} and $PM_{2.5}$ are highly limited, and recent literature suggests that where these effects are considered, independent respiratory effects attenuate to inconclusive or no effect levels (Ohlwein et al. 2019; Stacey 2019).

A recent study that evaluated aviation-related UFP exposure among children living near Schiphol Airport found that urban UFPs collectively, including from aviation, roadway, and other sources, could be independently associated with adverse respiratory effects. The study also found that, while aviation-related UFP exposure could be correlated to an increase in wheezing symptoms, "no consistent associations between aviation-related UFP with lung function was observed" (Lenssen et al. 2024). Another study has indicated strong correlations between the estimated lung-particle deposition and

biomarkers in exhaled breath from asthmatic children, which are suggestive of possible airway inflammation (Buonanno et al. 2012; Ohlwein et al. 2019).

A long-term 1.1 million adult cohort study in Toronto, Canada, initially found an increase in COPD cases associated with UFPs, but after correcting for co-pollutant effects, this association attenuated to inconclusive. This study, which remains some of the strongest epidemiological science, also found no observed increase in UFP-associated asthma or lung cancer (Weichenthal et al. 2017).

Neurological & Cognitive

Key Finding: The state of scientific evidence linking UFP exposure to neurological and cognitive effects remains highly limited and can be characterized as inadequate to infer a causal relationship.

Neurological and cognitive health endpoints are not commonly evaluated in the body of UFP literature. Biologically plausible exposure pathways do exist for UFPs to influence neurological endpoints. The same exposure pathways that might lead to cardiovascular health effects—deep penetration into lung tissues and transport across biological barriers—can result in UFPs circulating and diffusing into the nervous system and brain (Kwon et al. 2020). Alternative plausible biological pathways have also been hypothesized, including direct translocation through the olfactory nerve (Bandyopadhyay 2016).

Ohlwein et al.'s 2019 review found that only 4 out of 85 studies published between January 2011 and May 2017 considered neurological effects from aviation-related UFP exposure, and their findings were inconclusive regarding neurological health effects. Recent epidemiological research has expanded the body of science on UFP neurological effects, but studies remain limited. A long-term epidemiological study published in 2021 investigated the occurrence of malignant brain cancer in populations near LAX, tracking brain tumor and cancer cases over about 16 years. The study identified 155 total cases of malignant brain cancers over the studied population which was, in total, 12% more common in communities with higher exposure to aviation UFPs. There was no connection found between UFP exposure and meningioma (non-cancerous brain tumors) among the 420 cases studied (Wu et al. 2021). Although these findings support the idea that airport-related UFP exposure could be a risk factor in brain tumor development, the study did not correct for the effects of other aviation and urban non-aviation pollutants, making it impossible to draw causal connection without further research. Much of the body of current neurological research is cross-focused on reproductive and developmental effects.

Reproductive & Developmental Effects

Key Finding: Direct epidemiological evidence linking UFP exposure to reproductive or developmental outcomes in human populations remains limited and ranges from suggestive to inconclusive.

Reproductive health outcomes are frequently discussed as potential health concerns related to exposure to aviation UFPs. Toxicological studies in animals have provided clear evidence of biological plausibility, demonstrating that maternal exposure to UFPs, including BC, can induce stress, neurological inflammation, and increase the accumulation of misfolded proteins in the brains of offspring (Allen et al. 2014; Onoda et al. 2020). However, while these findings show that UFPs, in general, are capable of crossing biological barriers and interfering in neurological development, studies of this kind involve controlled, elevated exposures to highly specific particles; they are not representative of the real-world

magnitudes of exposures or particle chemistries (laboratory particles are typically diesel-derived) of UFPs from aviation activity.

Few epidemiological population-based studies have been evaluated for reproductive or developmental health endpoints specific to UFP from urban sources or aviation specifically. One study near LAX reported an association between modeled aircraft-related UFP exposure during pregnancy and increased risk of preterm birth (Wing et al. 2020). However, the observational nature of the study, a lack of significant additional corroborating studies at other airports, and the inability to correct for co-pollutant health contributions such as oxides of nitrogen, larger PM size fractions, aviation noise exposures, and other non-aviation pollutant exposures limit the causal findings to no more than suggestive. A more recent long-term exposure assessment near Amsterdam Schiphol Airport (AMS) reported possible associations between prenatal exposure to aviation-related UFPs and developmental outcomes, though findings were limited and not conclusive (Janssen et al. 2022). An ongoing study near Berlin–Brandenburg Airport (BER) is designed to study developmental outcomes in children exposed to aircraft-related UFPs (Soppa et al. 2023). While results are not yet available, additional long-term epidemiological studies on independent UFP reproductive and developmental effects which account for co-pollutant contributions will inform whether UFP-related effect attenuate to inconclusive, as shown with other discussed health endpoints, or continue to support suggestive associations.

States of the Evidence

The most current and comprehensive assessments of UFP health evidence consistently reflect the lowest of evidence classifications. In 2013, the Health Effects Institute (HEI) concluded that existing evidence was insufficient to attribute aviation-related health impacts to UFPs alone and emphasized the challenges in separating UFP health effects from those of co-pollutants, such as nitrogen oxides and $PM_{2.5}$ (HEI 2013; Stacey 2019). Ohlwein et al.'s 2019 review of short- and long-term exposure studies found that only 34 of the 85 studies attempted to adjust for one or more co-pollutants. The authors concluded that, for short-term inflammatory or cardiovascular effects, effects from UFP exposure "may be at least partly independent of other pollutants" but that for all other studied health outcomes "the evidence on independent health effects of UFP remains inconclusive or insufficient" (Ohlwein et al. 2019).

Among the most current meta-analyses, Bergmann et al. (2026) corroborated and expanded on this evidence gap, referencing research published through December of 2024 on 85 long-term exposure studies. In single-pollutant models evaluating UFP exposure (not aviation-specific and not correcting for co-pollutant variables), Bergmann et al. (2026) estimated a hazard ratio of 1.06 for natural mortality, with low confidence in the overall body of evidence. Similarly to HEI and Ohlwein et al, Bergmann et al.'s analysis concluded that fewer than half of the 85 long-term studies adjusted for co-pollutant exposure and that, with respect to causality, "the overall evidence for independent effects of long-term UFP exposure remains inadequate to low" (Bergmann et al. 2026).

While the pool of research has expanded significantly in recent years, few broad-scale multi-city epidemiological studies are available and fewer still attempt to isolate the effects of UFPs from the effects of $PM_{2.5}$ or for other co-pollutant effects. Of those that do, evidence remains inconsistent or

inconclusive for distinct and independent UFP health effects relative to those already addressed by existing $PM_{2.5}$ standards.

These conclusions underscore what further research might meaningfully advance the state of the science. While specific site studies can characterize local exposure conditions, these studies, by their nature and scale, cannot properly employ standard epidemiological exposure assessment methods, adjust for co-pollutant exposures, or implement the long-term follow-up durations needed to evolve the state of the science toward establishing independent "causal" or "non-causal" relationships. Until those foundational broad-scale epidemiological studies are completed, site or project-specific research cannot independently resolve gaps or draw evidence towards causal or non-causal associations, and should not be interpreted as a substitute for, or progress towards, such conclusions (Bergmann et al. 2026; Kumar et al. 2014).

Regulatory Trajectory of Ultrafine and Ultra-Ultrafine Particles

Under CAA section 231, EPA has exclusive authority to issue aircraft emission standards. In issuing these standards, EPA was directed by Congress to balance the health and environmental effects of aircraft emission standards against aircraft safety, cost and noise factors. Since 1973, EPA has issued a series of increasingly stringent aircraft emission standards for particulate matter, greenhouse gas emissions, nitrogen oxides, carbon monoxide and other conventional pollutants. To date, EPA has not regulated UFPs or UUFPs from aircraft emissions and has the exclusive authority to determine when and if the science will have matured to a point where aircraft emission standards might one day include standards for those ultrafine particulates.

Under Sections 108 and 109 of the Clean Air Act (CAA), the EPA periodically reassesses the health effects of pollutants regulated under the National Ambient Air Quality Standards (NAAQS), including PM. This process begins with the ISA, which synthesizes policy-relevant science and evaluates causality based on biological plausibility, epidemiological consistency, and other factors. Subsequent phases include the Risk/Exposure Assessment (REA) and the Policy Assessment (PA), which quantify risks and evaluate regulatory implications (EPA 2025d; EPA 2025e). The most recent ISA, issued in 2019 and supplemented in 2022, concluded there is high confidence in the causal relationship between $PM_{2.5}$ and adverse health effects, leading to more stringent $PM_{2.5}$ standards in 2024 (EPA 2022; EPA 2026a). In contrast, independent health effects of UFPs and UUFPs were classified as having evidence that is "suggestive of, but not sufficient to infer, a causal relationship," or "inadequate to infer" causality, based on limited and conflicting epidemiologic and toxicologic data and insufficient context to infer independent effects from $PM_{2.5}$ (EPA 2022).

In issuing its latest aircraft emissions rule, EPA emphasized that although it was aware of the MOV-UP study and related studies considering exposure to these pollutants from aircraft operating at SEA–they would decline to address these effects at that time (87 Federal Register [FR] 72312). Because EPA has the exclusive power to regulate these emissions, CAA section 233 prohibits local governments, including

the Port of Seattle, the Puget Sound Clean Air Agency, and the Washington Department of Ecology from imposing any standard for mitigation in consideration of these emissions.

Historically, PM regulation has evolved with advancing science: from total suspended particulates (TSP) in 1971, to PM_{10} in 1987, and $PM_{2.5}$ in 1997, with subsequent tightening in 2006, 2012, and 2024 (EPA 1987; EPA 2025a; EPA 2026a; EPA 2026b). These changes were driven by increasingly robust evidence linking fine particles to mortality and morbidity (EPA 2025b; EPA 2025c). While regulatory updates often lag behind scientific consensus due to the time required for ISA, REA, PA, and rulemaking processes, despite growing scientific interest, regulatory development for UFPs and UUFPs has not progressed due to insufficient causal evidence (EPA 2019; EPA 2022; EPA 2025d; EPA 2025e).

For UFPs and UUFPs, the state of future regulatory action will depend on the maturation of broad-scale epidemiological evidence capable of establishing independent causal health effects. Due to the scope and time scale required for such studies, it is not feasible or reasonable for a project-level study to ascertain the likelihood of health effects for UFPs or UUFPs.

Conclusions

This technical report discusses gaps in scientific knowledge relevant to potential UFP- or UUFP-related health impacts of the SEA SAMP NTPs. The current state of the evidence does not support independent causal UFP effects. Although biologically plausible health effect pathways do exist, the limited pool of epidemiological findings does not, to any extent, establish causal health effects from exposure to aviation UFPs or UUFPs that can be discerned as separate and distinct from effects experienced from exposure to $PM_{2.5}$ more broadly, from regulated aviation co-pollutants such as oxides of nitrogen, or from other co-pollutants ubiquitous to the urban background.

EPA has exclusive regulatory authority to control the emissions from aircraft. Gaps in the scientific understanding remain that have prevented EPA from regulating aviation UFPs or UUFPs to date. Studies detailing site-specific plume PNCs and source apportionment are plentiful within the corpus of available literature, including recent studies near SEA. The principal research needs to further the state of the science are broad, multi-year epidemiological studies that characterize the independent influence of UFP and UUFP exposure on health outcomes. Therefore, further studies at the project or site scale would not address these gaps or lead to meaningful additional insights on the health effects of exposure to UFPs and UUFPs.

1 Introduction

This appendix serves to supplement the Environmental Impact Statement (EIS) created for the Seattle-Tacoma International Airport (SEA) Sustainable Airport Master Plan (SAMP) Near Term Projects (NTPs), in accordance with Washington's State Environmental Policy Act (SEPA). In 2023, the State of Washington passed HB1181, which requires all local comprehensive plans to have a climate element. The Climate Synthesis Appendix provides a high-level review of the current and future climate threats in the Seattle region, the potential impacts of these threats to the SAMP NTPs, and an overview of existing and planned adaptation measures at SEA that can mitigate the potential impacts.

The scope of the Climate Synthesis Appendix is primarily focused on the SAMP NTPs. Climate threats were assessed through a literature review of national and regional sources. The review identified seven primary climate threats - Deficiency in Precipitation, Extreme Cold, Extreme Heat, Heavy Precipitation, Heavy Snow, Ice and Sleet, High Wind, and Wildfire. While sea level rise is a threat to the Seattle area and the Port, it is not considered a primary threat to SEA due to the Airport's elevation and distance from the shoreline. Impacts to the NTPs were broken down into eight functional categories, with an estimated risk level assigned to each climate threat. Existing and planned adaptation actions taken by SEA were then evaluated to determine whether they could be expected to mitigate the identified climate threats.

2 Affected Environment and Projected Future Climate Conditions

This section provides a high-level overview of key climate threats relevant to the proposed projects, along with a summary of historical conditions, observed climate trends, and projected future changes. These threats may pose risks to infrastructure, operations, and performance and are informed by regional climate data and established definitions of climate hazards. **Table 1** provides the historical condition and observed and future trends for each climate threat.

Table 1: Climate Threats in the Seattle Region

Threat	Historical Condition	Observed Trends	Future Trends
Deficiency in Precipitation	Seattle has historically benefitted from reliable precipitation and snowpack supporting water supply and hydropower	Summer precipitation has begun decreasing, with increasing instances of drought and reduced snowpack affecting seasonal water availability[1].	Continued decreases in summer precipitation, increased drought frequency, reduced snowpack, and greater stress on water supply and hydropower reliability[1,2].

[2] Climate Impacts Group, (2022). Biophysical Climate Risks and Economic Impacts for Washington State. Retrieved from https://cig.uw.edu/publications/biophysical-climate-risks-and-economic-impacts-for-washington-state/

Threat	Historical Condition	Observed Trends	Future Trends
Extreme Cold	Seattle's maritime climate typically has moderate winter temperatures, though historical records show occasional prolonged cold and snow events.	Overall warming trend, but periodic extreme cold events still occur due to Arctic air interactions.	Warmer average winters, but continued risk of episodic extreme cold events and occasional severe winter storms[3].
Extreme Heat	Historically mild summers, with relatively few extreme heat events.	Average summer temperatures have increased (~1.5 degrees F since 1950); notable extreme events such as the 2021 heat dome; increasing heatwave frequency.	Significant warming (projected +6.3 degrees F summer maximum); higher frequency and duration of heatwaves; increased risks to human health, infrastructure, and operations.[2]
Heavy Precipitation	Seasonal rainfall patterns with known flood-prone areas, including coastal and urban flooding	Increasing intensity and frequency of heavy rainfall events; more precipitation falling as rain rather than snow.	More intense and frequent extreme precipitation events; especially in winter; increased flood risk and strain on drainage systems; heaviest 24-hour rain events will intensify by 22% on average, by the 2080s.[1]
Heavy Snow, Ice, and Sleet	Moderate snowfall (avg. ~6 inches annually) with occasional large events; established airport response systems.	Episodic large snow events still occur (e.g., 2019), though overall variability remains high.	Potential for less frequent but still impactful snow/ice events; continued need for preparedness despite overall warming trends.[4]
High Winds	Regular winter wind events, with typical gusts of 40-45 mph and occasional severe events exceeding 90 mph.[5]	High wind events remain common, typically associated with winter storm systems.	Likely continuation of strong wind events, potentially increasing in intensity with stronger storm systems.

[5] King County, (2020). King County Regional Hazard Mitigation Plan 2020-2025. Retrieved from https://mrsc.org/getmedia/f5109483-ee3d-4e1e-b840-7704f50d77cf/k5rhmp.pdf

Threat	Historical Condition	Observed Trends	Future Trends
Wildfire	Historically, there has been lower wildfire risk in western Washington compared to eastern regions. Air quality has been impacted by smoke in the past.	Increasing wildfire frequency and intensity statewide due to warming temperatures and drier conditions. Increasing number of poor air quality days resulting from longer smoke seasons.	Longer fire seasons, increased frequency and area burned; moderate increases in western Washington risk, though still lower than eastern regions.[2] More wildfire smoke events worsening air quality.[1]

Overall, climate projections indicate that extreme heat, heavy precipitation, deficiency in precipitation, and reduced air quality from wildfire events will pose the greatest risks to the airport and proposed projects, with each threat expected to intensify in frequency, duration, and severity over time. These evolving conditions have important implications for infrastructure resilience, worker safety, and long-term operational reliability. Proactively addressing these key threats through design, planning, and adaptive management strategies is essential to proposed project performance under future climate conditions.

3 Potential Impacts to SAMP Projects

The SAMP includes capital improvement projects designed to meet SEA's Long-Term Vision to accommodate passenger levels and address identified needs for SEA over a 20-year planning horizon. Identified needs include the improvement of passenger experience at the airport, which is currently hindered by crowded spaces, long lines, and delayed flights. SAMP NTPs are meant to address near-term needs while the Port continues to evaluate long-term projects needed to address airfield and airspace limitations. Because the NTPs focus on a more immediate timeframe and address needs that are distinct from what may come from future planning, they were reviewed independently from the SAMP Long-Term Vision projects.

3.1 Potential Risk Summary

The proposed NTPs can be categorized into the following compartments: Airfield Projects, Terminal Projects, Cargo Projects, Landside Projects, Airport/Airline Support Projects, Relocated Building Projects, Demolished Building Projects, and Overall Program Support Projects. To assess potential impacts from the identified climate threats, projects within each of these categories were broken down into their major components. Relocated Building Projects are not evaluated as the projects within this category are included in other groups (Fuel Rack and Triculator fall within Airport/Airline Support Projects, and Portion of NAE falls within Landside Projects). **Table 2** provides an overview of the potential risk for each project type, which is described in further detail in sections 3.2-3.8. For this analysis, risk is assessed based on the likelihood of the climate threat, projected changes in its frequency and duration, and the perceived severity of the impact. The methodology used for this assessment is derived from the International Civil Aviation Organization (ICAO). After risk is calculated using likelihood and consequence, adaptive capacity is considered to determine whether or not the project will be vulnerable. These potential risks summarized below do not factor in the adaptative capacity at SEA airport, which are covered in Section 4.

Table 2: Potential Risk Summary by Project Type

Climate Threat	Airfield	Terminal	Cargo	Landside	Airport / Airline Support	Demolished Building	Overall Program Support
Deficiency in Precip.	Moderate	Moderate	Moderate	Moderate	Moderate	Low	Moderate
Extreme Cold	Moderate	Low	Low	Low	Low	Low	Moderate
Extreme Heat	Moderate	Moderate	Moderate	Moderate	Moderate	Low	High
Heavy Precipitation	Moderate	High	High	High	High	Low	High
Heavy Snow, Ice, Sleet	Moderate	Low	Low	Moderate	Moderate	Low	Moderate
High Winds	Moderate	Low	Moderate	Low	Moderate	Low	Moderate
Wildfire	Moderate	Moderate	Moderate	Moderate	Moderate	Low	Moderate

3.2 Potential Climate Impacts and Risk to Airfield Projects

Airfield Projects were evaluated based on the primary components of runways, taxiways, airfield operations, NAVAID's, airfield lighting, and signage. The airfield NTPs would upgrade portions of the airfield to meet current FAA airport design standards and improve an inefficient taxiway layout. **Table 3** summarizes potential impacts of climate threats and the estimated level of potential risk to Airfield Projects.

Table 3: Potential Climate Impacts and Risk to Airfield Projects

Airfield Projects		
Threat	**Potential Impacts**	**Potential Risk**
Deficiency in Precipitation	This threat could increase stress on pavement surfaces from soil contraction / subgrade shrinkage and reduce visibility from dust.	Moderate
Extreme Cold	Extreme cold could result in increased deicing operations, causing increased maintenance and potential flight delays. Refueling and servicing the aircraft may be delayed due to unsuitable conditions for workers. Repeat freezing and thawing can cause accelerated freeze thaw cycles, adversely impacting pavement integrity.	Moderate
Extreme Heat	Stress on taxiway pavements from increasing temperatures could cause asphalt to soften and deteriorate and lead to increased stress on electrical equipment, potentially causing	Moderate

	dysfunction, power outages, and disruptions to aircraft navigation and operations. Longer takeoff distances, reduced climb rates, and less thrust may reduce passenger loads and fuel capacity.	
Heavy Precipitation	Heavy precipitation could cause water damage to electrical infrastructure (including NAVAIDs), causing power outages and impacting flight operations. Storm events beyond a 25-year design storm may overload the drainage system. Water accumulation on runways and taxiways is unlikely, as previous vulnerability assessment identified no flooding for the 100-year storm. Flooding on aprons could lead to potential delays, impacting mobility around the airfield. Downstream creeks may experience increased flows resulting in flooding.	Moderate
Heavy Snow, Ice, and Sleet	Winter storm events could lead to damaged equipment. Snow may cause local utility outages. Accumulated snow or ice can block or hinder lighting systems. Increased use of deicing materials and other winter weather mitigation tactics may cause further deterioration. Accumulation of snow above bridges may weaken structural supports, increase the risk of collapse, and lead to mobility concerns for ground vehicles. Drain obstructions could occur due to frozen ground or snow causing flooding.	Moderate
High Winds	High winds may cause aircraft loss of control, aircraft damage, and airside infrastructure damage, resulting in costs, delays and maintenance. Stronger head winds can increase fuel usage and convective weather can force airplanes to extend their routes, thus increasing operational costs. Winds can damage above ground electrical equipment and signage, or deposit foreign object debris on the airfield, disrupting operations.	Moderate
Wildfire	Wildfires could cause power outages and air quality concerns, impacting visibility and leading to possible airfield closure.	Moderate

3.3 Potential Climate Impacts and Risk to Terminal Projects

Terminal Projects were evaluated based on the primary components of terminal, concourse, ramp, aprons, baggage handling operations, HVAC, and passenger services. The landside NTPs address the need for sufficient passenger processing facilities and gates to accommodate 56 million annual passengers at an optimal level of service. **Table 4** summarizes potential impacts of climate threats and the estimated level of potential risk to Terminal Projects.

Table 4: Potential Climate Impacts and Risk to Terminal Projects

Terminal Projects		
Threat	**Potential Impacts**	**Potential Risk**

Deficiency in Precipitation	Reduced water availability may limit cooling capacity, strain electrical systems, and disrupt potable and non-potable water supply. Prolonged drought conditions may cause soil contraction, leading to foundation movement and increased maintenance. Water restrictions may result in passenger discomfort and operational constraints.	Moderate
Extreme Cold	Increased heating demand may strain central utility systems and heating energy supply. Freezing temperatures may cause pipe failures, flooding, and damage to building materials. Repeated freeze–thaw cycles may accelerate pavement deterioration and increase maintenance needs. Cold conditions may reduce passenger comfort and affect outdoor terminal operations.	Low
Extreme Heat	High temperatures may increase cooling demand, stressing HVAC and energy systems. Thermal expansion may damage building components, vapor barriers, and mechanical systems. Overheating of electrical, baggage handling, and TSA equipment may disrupt operations. Heat exposure may pose health risks and reduce overall passenger comfort.	Moderate
Heavy Precipitation	Intense rainfall may cause flooding of utility corridors, parking facilities, and lower-level terminal areas. Water infiltration may damage electrical equipment and disrupt baggage handling and terminal operations. Flooding may restrict access to customer-facing facilities and ground transportation assets. Severe storms may result in localized or regional power outages affecting terminal services.	High
Heavy Snow, Ice, and Sleet	Snow and ice accumulation may damage roofs, pavements, and building systems, increasing maintenance needs. Snow and ice control activities may accelerate pavement wear and increase deicer use. Winter conditions may reduce passenger comfort and pose safety risks to workers and vehicles.	Low
High Winds	High winds may cause regional or local power outages, resulting in delays in operations. High winds may damage terminal structures, canopies, gates, and ground service equipment. Wind-driven debris may impact building envelopes and roof systems.	Moderate
Wildfire	Wildfires are unlikely to damage terminal structures due to buffer zones separating the airport from forested areas. Regional or nearby wildfires could cause operational risks from power shutoffs. Poor air quality may increase HVAC demand and strain the central mechanical plant (CMP). Smoke infiltration may pose health concerns for passengers and staff in the terminal.	Moderate

3.4 Potential Climate Impacts and Risk to Cargo Projects

Cargo Projects were evaluated based on the primary components of warehouse, office space, and ground transportation and logistics. The cargo NTPs address the deficiency in available facilities to accommodate projected cargo levels at the airport. **Table 5** summarizes potential impacts of climate threats and the estimated level of potential risk to Cargo Projects.

Table 5: Potential Climate Impacts and Risk to Cargo Projects

Cargo Projects		
Threat	**Potential Impacts**	**Potential Risk**
Deficiency in Precipitation	Very dry soil conditions could lead to soil subsidence or heaving, potentially affecting building foundations or underground utilities.	Moderate
Extreme Cold	Extreme cold could lead to premature brittle failure of materials such as seals, hoses, or fueling components.	Low
Extreme Heat	Heat waves or excessively high temperatures could lead to premature failure of some roofing components, pavement softening, and increased maintenance needs for HVAC equipment.	Moderate
Heavy Precipitation	Heavy precipitation could cause flooding of loading docks or cargo bays and potentially result in access issues if roadways were flooded.	High
Heavy Snow, Ice, and Sleet	Winter storms could cause structural stress due to roof loading and operational impacts due to ice and snow accumulation restricting access.	Low
High Winds	High winds could potentially damage warehouse roofs, doors, and siding, especially large bay doors.	Moderate
Wildfire	Regional or nearby wildfires could cause operational risks from smoke intrusion by exposing workers and/or sensitive cargo, and could increase HVAC filtration loads, causing systems to clog or fail, or to require additional maintenance.	Moderate

3.5 Potential Climate Impacts and Risk to Landside Projects

Landside Projects primarily consist of uncovered and covered parking facilities, roadways, and ground transportation. The landside NTPs address the existing parking constraints for employees and passengers, as well as the low level of service provided by the arrival and departure curbfronts during peak hours. **Table 6** summarizes potential impacts of climate threats and the estimated level of potential risk to Landside Projects.

Table 6: Potential Climate Impacts and Risk to Landside Projects

Landside Projects		
Threat	**Potential Impacts**	**Potential Risk**
Deficiency in Precipitation	Elevated temperatures and prolonged dry conditions may exceed pavement design thresholds, leading to rutting, reduced pavement service life, and increased maintenance requirements for pavement surfaces.	Moderate
Extreme Cold	Freeze–thaw cycles may cause cracking, potholing, heaving, and subsidence of pavements and structures, increasing maintenance needs and creating localized access and safety issues.	Low
Extreme Heat	Extreme heat may accelerate pavement deterioration, cause rutting or softening of asphalt surfaces, leading to increased maintenance and potential operational disruptions.	Moderate
Heavy Precipitation	Intense rainfall may overwhelm drainage systems, resulting in flooding of roadways, parking facilities, and lower levels of garages, which may restrict access, cause delays, and increase accident risk.	High
Heavy Snow, Ice, and Sleet	Winter storms may restrict roadway access; and elevate safety risks due to reduced traction, visibility, and mobility.	Moderate
High Winds	High winds may damage exterior facilities and canopies and create hazardous conditions for vehicles and pedestrians.	Low
Wildfire	Wildfires may result in roadway closures due to poor visibility, access limitations, and safety concerns.	Moderate

3.6 Potential Climate Impacts and Risk to Airport and Airline Support Projects

Airport and Airline Support Projects primarily consist of fueling infrastructure and operations, ARFF, deicing infrastructure and operations, and maintenance operations. These NTPs address the lack of fuel storage to meet projected demand, as well as SEA's SAF initiative. **Table 7** summarizes potential impacts of climate threats and the estimated level of potential risk to Airport and Airline Support Projects.

Table 7: Potential Climate Impacts and Risk to Airport / Airline Support Projects

Airport / Airline Support Projects		
Threat	**Potential Impacts**	**Potential Risk**
Deficiency in Precipitation	Prolonged drought conditions may cause soil contraction and foundation settlement, disrupt potable and non-potable water supply, and limit water availability for firefighting and facility operations.	Moderate
Extreme Cold	Extreme cold may pose safety risks to outdoor workers, require operational adjustments, and increase staffing needs. Freezing temperatures may cause pipe failures, brittle fuel system components, and disruptions to natural gas supply, resulting in operational delays.	Low

Airport / Airline Support Projects		
Threat	**Potential Impacts**	**Potential Risk**
Extreme Heat	Elevated temperatures may increase cooling demand and maintenance needs, stress HVAC infrastructure, and pose health risks to outdoor workers. It can also increase fueling risks by raising fuel volatility, leading to rapid evaporation and higher concentrations of flammable vapors.	Moderate
Heavy Precipitation	Intense rainfall may cause localized flooding, delay operations, contaminate fuel systems, and create unsafe working conditions due to reduced visibility and surface water accumulation.	High
Heavy Snow, Ice, and Sleet	Winter storms may delay operations, disrupt fueling activities, and increase safety risks for outdoor workers. Snow and ice may damage fuel system components, require additional deicing activities, and reduce operational efficiency.	Moderate
High Winds	High winds may damage aboveground fuel storage tanks and support facilities, create unsafe ramp conditions, and result in temporary operational shutdowns and flight delays.	Moderate
Wildfire	Wildfires may disrupt regional utility and fuel supply chains, increase fire and explosion risk, and cause power outages and operational delays due to safety concerns or preemptive shutdowns. Poor air quality may pose health risks to outdoor workers	Moderate

3.7 Potential Climate Impacts and Risk to Demolished Building Projects

Demolished Building Projects are included in the NTPs to enable the construction of other critical projects. While these projects will not exist in future climate conditions, the climate threats, potential impacts, and estimated potential risk associated with demolition operations are evaluated in **Table 8**.

Table 8: Potential Climate Impacts and Risk to Demolished Building Projects

Demolished Building Projects		
Threat	**Potential Impacts**	**Potential Risk**
Deficiency in Precipitation	This threat could result in an increased need for dust control.	Low
Extreme Cold	Prolonged exposure to extreme cold could lead to cold-related illnesses among construction workers, reduced production, and project delays. Construction materials, such as concrete and asphalt, have specific temperature requirements for proper curing and setting.	Low
Extreme Heat	Extreme heat could result in delays or suspension of work due to extreme heat and increased risk of heat-related	Low

	illnesses among workers, as well as potential damage to heat-sensitive materials.	
Heavy Precipitation	Excessive water could cause soil erosion, instability, and operational challenges which may disrupt or delay demolition processes.	Low
Heavy Snow, Ice, and Sleet	Snow, ice and sleet could create navigational challenges, reduced visibility, and delayed delivery of material supplies, resulting in project delays and downtime, and could lead to Increased safety risks for workers.	Low
High Winds	High wind could cause damages from fallen equipment and debris, resulting in increased costs and project delays.	Low
Wildfire	Wildfire could cause reduced air quality conditions at the airport, resulting in unsafe working conditions and poor visibility, and could potentially increase fire risks, especially near flammable materials. Poor air quality may lead to respiratory issues, fatigue, and other health problems, reducing productivity.	Low

3.8 Potential Climate Impacts and Risk to Overall Program Support Projects

Overall Program Support Projects include upgrades to stormwater infrastructure, utility systems, and the central mechanical plant (CMP). These projects are intended to enable SEA's long-term vision by addressing current needs across airport support systems. **Table 9** summarizes potential impacts of climate threats and the estimated level of potential risk to Overall Program Support Projects.

Table 9: Potential Climate Impacts and Risk to Overall Program Support Projects

Overall Program Support Projects		
Threat	**Potential Impacts**	**Potential Risk**
Deficiency in Precipitation	Reduced water availability may limit cooling capacity, strain electrical systems, and disrupt potable and non-potable water supply. Prolonged drought may cause soil contraction, leading to heaving, subsidence, and damage to underground utilities. Lower streamflows may increase sedimentation and pollutant concentrations and degrading water quality.	Moderate
Extreme Cold	Increased heating demand may strain the CMP. Freezing temperatures may cause pipe failures, frozen water cabinets, and damage to underground and surface infrastructure. Cold-related supply chain disruptions may delay delivery of fuel, utilities, and other critical materials.	Moderate
Extreme Heat	Elevated temperatures may increase cooling demand, stressing the CMP and requiring additional capacity. Thermal expansion may damage pipelines, storage tanks, and electrical components, increasing maintenance needs and outage risk. Higher temperatures may degrade water quality (e.g., nitrification), affecting potable water systems.	High

Heavy Precipitation	Intense rainfall may overwhelm stormwater systems, causing flooding of critical infrastructure. Flooding may damage electrical equipment, degrade water quality, and corrode infrastructure. Flood-related transportation disruptions may delay deliveries and maintenance activities.	High
Heavy Snow, Ice, and Sleet	Snow and ice may cause pipe failures, power outages, and reduced efficiency of power generation. Elevated deicer concentrations may affect stormwater treatment systems. Transportation disruptions may delay fuel, energy, and material deliveries.	Moderate
High Winds	High winds may damage buildings, antennae, and other aboveground facilities. Wind-induced power line damage may result in airport-wide power outages.	Moderate
Wildfire	Fire-related power shutoffs or damage to external utilities may disrupt airport power and fuel supply. Wildfires may degrade raw water supply and water quality. Regional infrastructure damage may result in prolonged supply chain disruptions. Wildfires may clog stormwater systems with ash and debris.	Moderate

3.9 Interaction of SAMP Projects with Regional Climate Trends

Proposed projects that increase water use, add impervious surfaces, or require additional electricity have the potential to interact with regional climate trends, including more frequent drought conditions, higher ambient temperatures, and more intense rainfall events. To avoid exacerbating these regional stressors, project designs can incorporate mitigation measures that improve long-term environmental performance and climate resilience. Water-using systems can be designed for high efficiency and may include reuse or recirculation features to limit potable demand during drought periods. Added impervious areas can be managed through stormwater controls sized for projected increases in rainfall intensity, including enhanced detention, infiltration, and low-impact development practices where feasible. Electrical systems and building envelopes can emphasize energy efficiency, reduced heat gain, and support for renewable or low-carbon energy sources to offset higher cooling loads associated with rising temperatures. These design decisions can minimize adverse interactions with changing climate conditions while maintaining compliance with applicable environmental requirements.

4 Adaptation Practices

The Port of Seattle has implemented and will continue to advance a variety of measures to improve resilience to climate-related risks and support long-term sustainability. These actions address both infrastructure resilience and operational sustainability, helping the airport adapt to changing climate conditions such as increasing temperatures, heavier precipitation events, and changes in extreme weather patterns. The Port integrates climate adaptation into planning, design, and operations through established sustainability programs, infrastructure management practices, and strategic policy goals.

4.1 Existing Adaptation Practices

Several existing climate adaptation practices focus on improving the resilience of airport infrastructure and resource systems. The Port's Sustainable Evaluation Framework (SEF) plays a central role in incorporating resilience into capital project planning. This framework applies to capital projects and organizes them into tiers based on project size and sustainability opportunities. Projects with significant sustainability potential convene a Sustainable Project Assessment and Review Collaboration (SPARC) team, which evaluates early design opportunities and recommends sustainability and resilience concepts. These recommendations are documented in a Sustainable Design Approach presented to the Port Commission and ultimately incorporated into a project's Sustainable Design Strategy. The Port also encourages the use of other third-party frameworks such as Envision and LEED. Projects utilizing these frameworks may evaluate and assess potential risks from climate change. By evaluating resilience and sustainability considerations early in the planning and design process, these frameworks support the integration of resilience-oriented initiatives across the airport campus.

4.1.1 Water

The Port works to maximize the conveyance capacity of stormwater infrastructure through the stormwater utility master plan, as well as on a project-by-project improvements to airport drainage systems. Findings from the Airport's Climate Vulnerability Assessment have also been incorporated into stormwater utility planning to respond to evolving precipitation patterns. Water conservation measures have been implemented across airport facilities, including capturing rainwater from the North Satellite roof to supply restrooms with graywater, installing secondary "purple pipe" systems to enable water reuse where available, establishing water-efficient landscaping standards, and implementing National Pollutant Discharge Elimination System (NPDES) permit measures that allow Industrial Wastewater System (IWS) water to be reused for dust suppression, irrigation, and other construction-related activities. Water conservations measures can increase the Airport's resilience to drought and help minimize its impacts to regional water supplies.

4.1.2 Energy

Energy efficiency, fuel diversification and adequate back-up power systems are also key components of the airport's adaptation approach. SEA has implemented ongoing monitoring of airport energy use relative to ambient air temperatures to better understand climate-related energy demand patterns. The airport has retrofitted older lighting systems with energy-efficient LED lighting and requires new construction projects to meet LEED Silver certification or higher, which incorporates energy and water efficiency strategies. Additional Energy Efficiency Measures have been identified for the airport through the Clean Buildings Performance Standard, which will further reduce electricity and natural gas demand.

Fuel diversification has occurred across the airport's on-road fleet, in its generators, and for building heating. These initiatives include the use of renewable diesel for heavy-duty equipment such as snowplows and sweepers, renewable natural gas in its bus fleet, and electrification of Port-owned vehicles where feasible. The airport's heating system uses a mix of natural gas and renewable natural gas and can also run on renewable diesel or traditional diesel in emergencies. This system is expected to be further

diversified and resilient by moving the airport's central mechanical plant to ground source heat and hot water, rather than natural-gas powered steam.

These operational practices and project-level strategies support the Port of Seattle's broader sustainability commitments under the Century Agenda, which includes goals to meet all increased energy needs with conservation and renewable sources, meet or exceed regulatory requirements for stormwater leaving Port facilities, and reduce projected future water consumption by 12 percent by 2030. Complementary programs such as the Aviation Utilities Group's Energy Efficiency Incentive (EEI) funding further encourage the implementation of energy-efficient equipment and designs that exceed minimum code requirements. Energy conservation measures can also help SEA manage demand and free up capacity to account for demand from future increased temperatures.

In 2018, the airport built an Alternative Utility Facility. The AUF includes 10 generators, a control building, Medium Voltage (MV) switchgear building, and MV automatic transfer switching building, situated on a secure campus linked to SEA's main substation by MV underground ducts. Its main objective is to enhance the airport's ability to withstand utility failures by assuming control of the crucial 115kv feed. The AUF houses dual-fuel generators capable of operating on traditional diesel, renewable diesel, jet fuel and SAF or alternative jet fuel. The system ensures continuous or near-continuous uptime, delivering a reliable 30 megawatts of power through ten 3 MW generators.

4.2 Planned Adaptation Measures

In addition to these existing practices, the Port has identified several planned adaptation measures to strengthen resilience in the future. As airport infrastructure is replaced or upgraded, design standards will be updated to account for climate threats, including increased rainfall intensity and higher summer temperatures. The Port also plans to further integrate climate considerations into future utility master planning; including upgrading the Central Mechanical Plant to ground source heat instead of natural gas and re-examining design criteria for stormwater systems to accommodate larger design storm events off the airfield where feasible. Operational improvements are also planned, including avoiding electrical conductor splicing in underground vaults to reduce vulnerability, implementing systems within the Maximo asset management platform to track weather-related repairs and replacements, and continuing the conversion of gas- and diesel-powered ground support equipment to electric alternatives.

Future initiatives will also focus on fuel diversification and emissions reduction, which enhance operational resilience while reducing greenhouse gas emissions. The Port has developed a Sustainable Fleet Plan to transition fleet vehicles to cleaner fuels and continue expanding electrification. The Port of Seattle has also established one of the most ambitious sustainable aviation fuel (SAF) strategies in the United States, with the goal of ensuring that every flight fueled at SEA uses at least a 10 percent blend of sustainable aviation fuel by 2028. Together, these existing and planned initiatives strengthen the airport's ability to adapt to changing climate conditions while supporting long-term sustainability and operational reliability.

5 Conclusion

The greatest threats to the SAMP NTPs are from heavy precipitation events, closely followed by extreme heat, drought, wildfire (primarily from air quality and regional impacts), and high winds. The climate science review identified that seven climate threats, extreme heat, heavy precipitation, deficiency in precipitation, and wildfire are expected to worsen in the Seattle region. This emphasizes the importance of addressing heavy precipitation, extreme heat, and deficiency in precipitation in the SAMP NTPs.

SEA already has robust environmental and sustainable design programs and procedures in place to maximize resilience. Climate projections of worsening extreme precipitation have been incorporated into the stormwater utility master plan and into individual project improvements to airport drainage systems. Key operational practices such as the Port's Sustainable Evaluation Framework (SEF) and use of third party frameworks play a critical role in incorporating resilience into capital project planning. These processes allow individual projects to evaluate resilience and sustainability considerations early in the planning and design process, which will support the climate resilience of the SAMP NTPs. Overall, the Port's existing and planned adaptation actions are well matched to address the potential impacts to the SAMP NTPs from climate change. **Table 10** provides a crosswalk between the identified climate threats and the adaptation measures that increase SEA's resilience.

Table 10: Threats and Adaptation Actions

Threat	Adaptation Action
Deficiency in Precipitation	Individual project geotechnical investigations evaluate soil conditions and susceptibility to movement. Future projects may include water conservation measures which help mitigate the intensity of drought conditions.
Extreme Cold	This threat is not expected to worsen. Current airport operational procedures and design processes should be sufficient to cope with extreme cold events.
Extreme Heat	As assets are replaced, the airport will confirm they accommodate higher summer temperatures (via design criteria). Monitoring the airport's energy use relative to ambient air temperatures is on-going. Future energy efficiency measures will help mitigate additional demand needed for more extreme heat days.
Heavy Precipitation	As assets are replaced, the airport will confirm they accommodate increased rainfall intensity (via design criteria). SEA will continue to maximize conveyance capacity of the airport on a project-by-project basis. The Airport is re-examining the airport's design criteria (e.g., increasing to a 50- or 100-year storm event where possible) and conveyance modeling, particularly for stormwater systems.
Heavy Snow, Ice, and Sleet	This threat is not expected to worsen. Current airport operational procedures and design processes are expected to be sufficient to address winter storm events.
High Winds	High winds are currently included in SEA's design standards. Potential power outages due to high winds are addressed through the airport's Alternative Utility Facility generators.
Wildfire	Projects are expected utilize the SEF structure or other frameworks which may consider potential impacts from wildfires related to air quality.
