POLLUTION CONTROL HEARINGS BOARD  
FOR THE STATE OF WASHINGTON

AIRPORT COMMUNITIES COALITION, )  
Appellant, )  
v. )  
STATE OF WASHINGTON, )  
DEPARTMENT OF ECOLOGY; and )  
THE PORT OF SEATTLE, )  
Respondents. )

No. 01-133

DECLARATION OF DR. JOHN  
STRAND IN SUPPORT OF ACC'S  
MOTION FOR STAY

(Section 401 Certification No.  
1996-4-02325 and CZMA concurrency  
statement, issued August 10, 2001,  
Related to Construction of a Third  
Runway and related projects at Seattle  
Tacoma International Airport)

Dr. John Strand declares as follows:

1. I declare the following from personal knowledge and am competent to testify thereto before the Board if necessary.

2. I am an internationally recognized fisheries biologist with over 25 years experience specializing in studies to determine potential effects of human activities on aquatic resources. I received my Ph.D. in Fisheries Biology from the University of Washington in 1975 and currently am the Principal Biologist for Columbia Biological Assessments. I am also an adjunct faculty member of the Environmental Sciences and Regional Planning Program at Washington State University Tri-Cities. I am a Certified Fisheries Professional and have extensive experience assessing the ecological risks from discharges of contaminants to surface

DECLARATION OF DR. JOHN STRAND IN  
SUPPORT OF ACC'S MOTION FOR STAY - 1

HELSELL FETTERMAN LLP

1 waters on sensitive aquatic species and their habitats. I also have substantive local knowledge,  
2 having studied the fate of stormwater residuals in both Miller and Des Moines Creeks for the  
3 Airport Communities Coalition (ACC), an organization composed of the Cities of Burien, Des  
4 Moines, Federal Way, Normandy Park and Tukwila and the Highline School District. With the  
5 King County Department of Natural Resources, I also recently investigated the fate and effects of  
6 combined sewer overflows on aquatic life in the Duwamish River. In addition, a considerable  
7 part of my professional career has been spent evaluating the environmental impacts of engineered  
8 structures on water resources including a wide variety of projects and field studies in  
9 Washington, California, Alaska, British Columbia, Guam and Venezuela. Attached hereto as  
10 Exhibit A is a true and correct copy of my Curriculum Vitae.

11  
12  
13 3. I understand that the ACC has filed an appeal with the Pollution Control Hearing  
14 Board (NPCHB) challenging the Washington Department of Ecology's (Ecology) Water Quality  
15 Certification (Order #1996-4-02325) for the Port of Seattle's (Port) Master Plan Update  
16 Improvements for Seattle-Tacoma International Airport (STIA). I also understand that ACC has  
17 requested a stay of the effect of the Water Quality Certification until the questions it has raised  
18 concerning compliance with the Clean Water Act have been resolved by the PCHB. I am  
19 submitting this declaration in support of ACC's appeal and motion for stay because I am  
20 convinced that Ecology's 401 Water Quality Certification will not protect the valuable and  
21 remaining water resources around STIA and will, in fact, result in likely harm to these sensitive  
22 streams and their aquatic life.  
23  
24

25  
DECLARATION OF DR. JOHN STRAND IN  
SUPPORT OF ACC'S MOTION FOR STAY - 2

AR 021409

1           4.     I have previously reviewed and evaluated the database that the Port submitted to  
2 Ecology in support of their request for a Water Quality Certification. Attached hereto as Exhibit  
3 B is a true and correct copy of comments that I submitted to Ecology on December 13, 1999, on  
4 behalf of the Citizens Against SeaTac Expansion. While this comment letter set forth my  
5 opinion regarding the impacts of the Port's stormwater on the project creeks, I am submitting this  
6 declaration to reiterate, reinforce, and expand on my opinion that the project creeks are valuable  
7 water resources worthy of the Board's utmost review and Clean Water Act protection.  
8

9           5.     In preparing this declaration, I have reviewed the documents and scientific  
10 literature listed in Exhibit C. In addition, I have, on behalf of and with the help of the ACC,  
11 conducted water quality sampling surveys in the streams surrounding STIA: In April and August  
12 2000, corresponding to the wet and dry seasons, respectively, water, sediment, and fish tissue  
13 samples were collected at selected sites in Miller and Des Moines Creeks. The objective of this  
14 sampling was to determine the nature, extent, and potential sources of pollution entering or  
15 already present in Miller and Des Moines Creeks. Chemicals of particular interest were heavy  
16 metals, petroleum hydrocarbons, and other organics (glycols). In continuing investigations,  
17 conventional water quality measurements (temperature, pH, turbidity, hardness, dissolved  
18 oxygen, nutrients) are conducted at the same sites monthly. Actual and suspected pollution  
19 events are also investigated as they occur. Sampling, sample handling, and analyses follow  
20 methods outlined in PSEP (1996a, 1996b, 1996c) or by the USEPA (1979). A Washington

1 Department of Ecology certified analytical laboratory performs the metals and organic chemical  
2 analyses.

3           6. For the reasons presented in this declaration, I believe there is evidence that  
4 violations of Toxic Substances (water quality) Criteria in Miller Creek and Des Moines Creek,  
5 particularly for copper, lead, and zinc, occur as a result of stormwater discharged by the STIA,  
6 and will continue, and potentially worsen as a result of the Port's Master Plan Update  
7 Improvements. Glycols associated with de-icing of aircraft at STIA are routinely found in winter  
8 in the project creeks at concentrations known to be toxic to fish and other aquatic life. Periodic  
9 whole effluent testing of stormwater from the Port's outfalls documents residual toxicity,  
10 highlighting the need for stormwater treatment. Although the Port indicates they will retrofit all  
11 stormwater outfalls that do not currently receive treatment to improve water quality, looking  
12 closer at the Port's *Comprehensive Stormwater Management Plan* (Parametrix 2000a) indicates  
13 that a final decision on retrofitting has not been made and that evaluation continues. In other  
14 cases, the Port indicates that costs of retrofitting may be prohibitive, suggesting that retrofitting is  
15 not certain. There also is evidence that fill already stockpiled by the Port at STIA, contains  
16 residual chemicals (PCBs and DDT) that have the potential to percolate the fill pile to  
17 groundwater, ultimately contaminating area wetlands and surface waters. Flow reductions in  
18 project streams as a result of the proposed airport construction and operation have not been  
19 established with any degree of accuracy with the result that simulations conducted by the Port  
20 may underestimate summer low-flow impacts and overestimate the contributions of proposed  
21  
22

AR 021411

1 mitigation and natural mitigating factors. Finally, in the context of addressing low flows on the  
2 project streams, the Port's management approach to monitor the quality of detained or discharged  
3 stormwater, and only when a problem is encountered, take steps to mitigate impacts, doesn't  
4 provide reasonable assurance that valued aquatic resources will not be impaired.  
5

6 7. Although disturbed, the project streams (Miller Creek, Walker Creek, Des Moines  
7 Creek, Gilliam Creek) still support a diverse and abundant fish fauna and are worthy of  
8 protection. Both coho and chum salmon are known to spawn and rear in Miller Creek, Walker  
9 Creek, and Des Moines Creek. (Hillman et al. 1999). Chinook salmon frequent the outfalls of  
10 Miller and Des Moines Creeks in Puget Sound during their outmigration (Parametrix 2000a).  
11 Both the Miller Creek and Des Moines Creek Watersheds are also exploited by resident cutthroat  
12 trout (Parametrix (2000a); Miller Creek may include an anadromous race of cutthroat trout.  
13 Warm water fish species including yellow perch, black crappie, largemouth bass, and  
14 pumpkinseed sunfish have been found in the upper reaches of both watersheds (Parametrix  
15 2000b). Prickly sculpin, three-spined stickleback, and crayfish also occur throughout each  
16 watershed (Parametrix 2000b). Gilliam Creek supports many of the same species of fish as  
17 found in Miler Creek, Walker Creek and Des Moines Creek. Of considerable interest and  
18 importance is the recent finding of juvenile Chinook salmon in Gilliam Creek (personal  
19 communication, April 2000, Ryan Partee, City of Tukwila, Tukwila, Washington). Chinook is a  
20 listed species under the Endangered Species Act.

Spokane, WA 99201

AR 021412

1           8.       In the context of what is known about the natural resources of the project streams,  
2 it should be pointed out that the Port's analyses of impacts for the proposed Master Plan Update  
3 Improvements are inadequate because the Port has yet to undertake a quantitative survey of the  
4 fish and other aquatic organisms found in the project streams. In other words, the Port has not  
5 established a baseline condition. This is a critical deficiency because the appropriateness of  
6 regulatory approval and mitigation must be assessed, using this baseline, before approval of the  
7 proposed project can be granted.  
8

9           9.       Several constituents (metals, fecal coliforms, turbidity) associated with STIA  
10 stormwater in Miller and Des Moines Creeks have historically and presently violate State of  
11 Washington (State) Water Quality Criteria (Chapter 173-201A WAC). Exceedances of water  
12 quality criteria for the metals copper, lead, and zinc are of particular concern given their  
13 designation as Toxic Substances. Metals data from 1995-1996, presented by the Port in 1997,  
14 indicated that concentrations of copper, lead, and zinc in STIA stormwater discharges (at outfall)  
15 greatly exceeded State and U.S. Environmental Protection Agency (USEPA) Toxic Substances  
16 Criteria, in some instances by more than an order of magnitude. For example, at the stormwater  
17 outfall to Miller Creek (see 1997 report page 35), total recoverable copper concentrations ranged  
18 from 4.2-82.9 ug/L. The State's criterion is 5.3 ug/L. The Port's 1997 data also indicated that  
19 concentrations (4.7-14.8 ug/L) of total copper upstream of STIA exceeded the State's criteria.  
20 That Miller Creek was unable to assimilate the STIA discharges, however, is confirmed by  
21 downstream sampling data showing total copper concentrations of 0.72-44 ug/L. In other words,  
22  
23  
24

25

Rachael Paschal Osborn  
Attorney at Law  
2421 West Mission Avenue  
Spokane, WA 99201

1 even after dilution in Miller Creek, the concentrations of copper still exceed Water Quality  
2 Criteria. For total recoverable lead in Miller Creek, the values at the outfall, upstream, and  
3 downstream were <0.5-21.6 ug/L, 5.2-34.7 ug/L, and <0.5-106 ug/L, respectively, again showing  
4 that the influence of lead additions at the outfall persist downstream. The State criterion for lead  
5 is 16 ug/L. The values for total recoverable zinc at the outfall, upstream, and downstream were  
6 15-525 ug/L, 37-69 ug/L, and 2.3-295 ug/L., respectively, again showing a similar relationship.  
7 The State criterion for zinc is 33.7 ug/L. Based on the dissolved metals concentrations (see data  
8 presented on page 35), Toxic Substances Criteria are still exceeded by as much as an order of  
9 magnitude.  
10

11  
12 10. It is evident that the concentrations of copper, lead, and zinc downstream of the  
13 discharges exceeded applicable toxic substances criteria. In their various reports, the Port also  
14 does not provide evidence that would support a scientifically valid conclusion that stormwater  
15 from STIA does not impact either Miller or Des Moines Creeks downstream of their respective  
16 outfalls. Persistence of the influence of stormwater downstream, and at the magnitudes  
17 illustrated above suggests the need for treatment of the waste streams, or connections to the  
18 Industrial Waste System (IWS).  
19

20 11. Metals data from 1998-1999, presented by the Port in 1999, confirm that  
21 exceedances of toxic metals criteria continued to occur at the Port's stormwater outfalls to the  
22 creeks. In addition, the downstream stations, where sampled, show that the influences of STIA  
23 stormwater discharges persist in the receiving waters. What appears missing in the 1999 report,  
24

AR 021414

1 however, is any indication that the Port sampled upstream of STIA. The Port's failure to  
2 maintain the original sampling protocol in this regard greatly diminishes the value of their  
3 stormwater-monitoring program. Data presented by the Port in their most recent Annual  
4 Stormwater Monitoring Report (2000) confirm that exceedences of toxic metals criteria in the  
5 Port's stormwater discharges continue today.  
6

7 12. In my opinion, STIA stormwater adversely impacts the water quality of Miller and  
8 Des Moines Creeks. The Port's sampling data confirms that STIA stormwater greatly contributes  
9 to exceedences of toxic metals criteria in the receiving waters.  
10

11 13. The 1997, 1999, and 2000 Annual Stormwater Reports prepared by the Port  
12 include comparator concentrations for metals, fecal coliforms, turbidity and other water quality  
13 parameters in stormwater. Comparator concentrations are based on stormwater data collected by  
14 other authorities (e.g., City of Bellevue, City of Portland). These comparators are found in Table  
15 21 in the Port's 1997 report, in table 4 in the Port's 1999 report, and in Table 4 of the 2000  
16 report. While these data maybe of some scientific interest, these data do not address the question  
17 of whether documented exceedances in water quality criteria in Miller and Des Moines Creeks  
18 are attributable to stormwater discharges from STIA. What is germane in this case is a  
19 comparison of the concentrations of metals discharged to Miller and Des Moines Creeks with the  
20 applicable State Water Quality Criteria. It really doesn't matter if the concentrations of metals in  
21 Miller Creek are the same as the concentrations of metals occurring in surface waters near  
22  
23

AR 021415

1 Bellevue or Portland. All this means is that the Cities of Bellevue and Portland are also not in  
2 compliance with applicable Water Quality Criteria.

3  
4 14. Additional evidence that STIA stormwater adversely affects the aquatic resources  
5 of Miller Creek is found in the sediments below Lake Reba, into which the Port discharges its  
6 stormwater (Port 1997 [see Table 4]). Values for copper in sediments from three samples above  
7 Lake Reba were 17.4, 8.4, and 9.9 mg/Kg dry weight, while copper in sediments from three  
8 samples below lake Reba were 22.3, 47.8, and 19.7 mg/Kg dry weight. The quantities of copper  
9 below the impoundment are substantially greater than the quantities of copper above the  
10 impoundment. A similar relationship for lead exists above and below Lake Reba. Lead in  
11 sediments from three samples above Lake Reba were 39, 34, and 38 mg/Kg dry weight, while  
12 lead in sediments form three samples below Lake Reba were 77, 172, and 56 mg/Kg dry weight.  
13 Levels of zinc in three samples above Lake Reba were 105, 90.2, and 94.1, mg/Kg dry weight,  
14 while zinc values in three samples below Lake Reba were 165, 402, and 148 mg/Kg dry weight.

15  
16 15. While Washington has not adopted Sediment Quality Standards-Chemical Criteria  
17 for Freshwater Sediments, the copper, lead, and zinc values in sediments below Lake Reba  
18 exceed standards adopted in Canada, which are good indicators of water quality problems. For  
19 example, all the values for copper in sediments below Lake Reba exceed the Lowest Effects  
20 Level (16 mg/Kg dry weight) for copper from the Guidelines for the Protection and Management  
21 of Aquatic Sediments in Ontario (Persuad et al. 1993). Similarly, all the values for lead and zinc  
22 in sediments below Lake Reba exceed the Lowest Effects Levels for lead (31 mg/Kg dry weight)  
23  
24

25  
DECLARATION OF DR. JOHN STRAND IN  
SUPPORT OF ACC'S MOTION FOR STAY - 9

AR 021416

1 and zinc (120 mg/Kg dry weight) from the Guidelines for the Protection and Management of  
2 Aquatic Sediments in Ontario Guidelines (Persuad et al. 1993). (Lead in sediments above Lake  
3 Reba also exceeds the Canadian Guidelines but only slightly.) This is some of the most  
4 compelling evidence that stormwater from STIA has impacted Miller Creek. Based on the  
5 Canadian Guidelines, there is a high probability that sediment concentrations of copper, lead, and  
6 zinc occurring below Lake Reba are toxic to greater than five percent of the aquatic genera  
7 inhabiting this site.

9 16. While it is unknown precisely how far downstream the impacts of copper, lead,  
10 and zinc occur in Miller Creek and Des Moines Creek, it is evident from recent (April and  
11 August 2000) ACC water quality surveys, that copper, lead, and zinc are bioavailable to aquatic  
12 life in both Miller and Des Moines Creeks. Copper, lead, and zinc residue levels in cutthroat  
13 trout from upper Miller Creek (S 157<sup>th</sup> PL crossing) were 6.5, 0.31, and 137 mg/Kg dry weight,  
14 respectively in the wet season (April). The dry season (August) data at the same location on  
15 Miller Creek were 6.5, 0.74, and 145 mg/Kg dry weight, respectively. Comparable data from  
16 upper Des Moines Creek (S 200<sup>th</sup> Street crossing) collected in the wet season (April) were 4.3,  
17 0.34, and 129 mg/Kg dry weight, respectively. No trout were collected at this location during the  
18 dry season. While Washington has not adopted water quality standards based on tissue residue  
19 concentrations, the lead and zinc concentrations found in cutthroat trout in the upper reaches of  
20 both Miller Creek and Des Moines Creek exceed the tissue screening concentrations (TSCs) for  
21 lead (0.32 mg/Kg dry weight) and zinc (100 mg/Kg dry weight) used by Shepherd (1999) in  
22  
23

AR 021417

1 ecological risk assessments. These data indicate that lead and zinc are chemicals of concern that  
2 require more detailed investigation and additional control.

3  
4 17. Glycol-based de-icers and anti-icers, used in de-icing aircraft at STIA, which are  
5 required to drain only to the IWS are also presently found in the project streams. The Port's  
6 Annual Stormwater Monitoring Reports for 1999 and 2000 indicate that glycols occur in  
7 stormwater at STIA outfalls that discharge both to Miller and Des Moines Creeks. While the  
8 IWS at STIA is designed to collect aircraft de-icers and anti-icers reaching the tarmac, glycols in  
9 de-icers and anti-icers are still routinely detected at six of the Port's stormwater outfalls: SDN1,  
10 SDN2, SDN4, SDE4, SDS1, and SDS3. Outfalls SDN1, SDN2, and SDN4 are located on the  
11 north end of the STIA and discharge to Lake Reba on Miller Creek. Outfalls SDE4, SDS1, and  
12 SDS3 are located at the south end of STIA and discharge to the East Tributary or Northwest  
13 Ponds on Des Moines Creek.  
14

15 18. The concentrations of glycols entering the project streams vary widely and are not  
16 trivial. For example, glycols of 12, 810, and 364 mg/L were found in SDE4, SDS1, and SDS3  
17 outfall discharges, respectively, following aircraft de-icing on January 11-12, 2000 (Port 2000).  
18 The most recent data from February 2001, indicated that glycols of 46.7, 48.7 and 419.4 mg/L  
19 were found in stormwater being discharged from the same three outfalls, respectively (Port  
20 2001). The majority of the glycols at each discharge were propylene glycol.  
21

22 19. The ACC also detected propylene glycol in duplicate samples from Des Moines  
23 Creek on February 9 and 19, 2001 at S 200<sup>th</sup> Street, just south of the Tyee Valley Golf Course.  
24

Spokane, WA 99201

AR 021418

1 Propylene glycol was not detected in duplicate samples on either of these dates in the West  
2 Tributary of Des Moines Creek at 192<sup>nd</sup> Street, which is above any known influence of STIA.  
3 These finds suggest that this glycol entered Des Moines Creek on the West Tributary below  
4 192<sup>nd</sup> Street, or entered on the East Tributary somewhere above the confluence of the West and  
5 East Tributaries. The likely source of this contamination was one of the STIA outfalls: SDE4,  
6 SDS1, or SDS3. The concentrations of propylene glycol in these four samples ranged between  
7 11 and 17 mg/L. Because this is propylene glycol, the source is likely an aircraft anti-icer and  
8 not an aircraft de-icer or auto/truck anti-freeze that are mainly ethylene glycol based.  
9

10 20. At issue is the toxicity of the de-icing or anti-icing agents. In particular, it is the  
11 presence of additives in the commerce de-icer or anti-icer that account for most of the toxicity  
12 (Hartwell et al 1995). Some examples of additives found in de-icers and anti-icers that may  
13 affect toxicity include: sodium nitrite, sodium benzoate, borax, diethylene glycol, ethylene oxide,  
14 acetaldehyde, dioxane, high-molecular weight polymers, polyamines, triazoles, and urea,  
15 (MacDonald et al. 1992; Hartwell et al. 1995; Lokke 1984).  
16

17 21. It is my opinion that de-icers and their additives can be toxic to aquatic life at  
18 relatively low concentrations (1.8-8.7 mg/L), which I base on the work of Hartwell et al. (1995).  
19 Hartwell et al. (1995) determined that the 7-day LC<sub>50</sub> for commercial anti-icer to fathead minnow  
20 ranged between 24.2 and 43.3 mg/L, based on the concentration of total glycols in the test  
21 solution. By definition, these results indicate that the LC<sub>25</sub> or LC<sub>10</sub> (the concentrations killing  
22 25% and 10% of the test population in 7 days) will occur at lower concentrations of total glycols,  
23

1 that is, in the range of glycol concentrations found recently by the ACC. Hartwell et al. (1995)  
2 also observed that gill pathology (edema, respiratory cell hypertrophy, and proliferative  
3 bronchitis) occurred in fish exposed to anti-icer at 17.6 mg/L propylene glycol. It is reasonable  
4 to assume that a fish with these symptoms will die if the exposure continued at this same level.  
5 Hartwell et al. (1995) also observed toxicity and similar gill pathology in fathead minnows  
6 exposed to stormwater from a stream receiving winter runoff from a large commercial airport. In  
7 these tests, which included detailed chemical monitoring, the LC<sub>50</sub> ranged between 1.8 and 5.4  
8 mg/L total glycols. The concentrations of total glycols cited in the 1999 and 2000 Annual  
9 Stormwater Monitoring Reports, and in the February 2001 stormwater analyses (Port 2001) also  
10 exceed the concentrations reported by Hartwell et al. (1995) to be toxic to aquatic life.  
11  
12

13 22. Whole effluent testing of STIA stormwater as required in their National Pollution  
14 Discharge Elimination System Permit has also detected toxicity in the Port's stormwater (see  
15 Table 7-15, page 7-25, *Biological Assessment* [Parametrix 2000b]). In effluent from SDN1, the  
16 percent survival of daphnia ranged between 10 and 80 percent over three test dates, the most  
17 recent 1/24/99. Mean survival over these three tests was only 40 percent. Percent survival of  
18 fathead minnow ranged between 40 and 78 percent, with a mean of 60 percent. Whole Effluent  
19 Testing (WET) at the Port's stormwater outfalls also demonstrates that at two other outfalls  
20 (SDN4 and SDE4), percent survival was as low as 75 and 63 percent, respectively, on at least one  
21 of the four dates when tests were conducted, indicating that toxicity occurs more often than the  
22 Port would have us believe. This level of toxicity is not trivial and indicates that acute (short-  
23

1 term) toxicity of fish and other aquatic life can occur in Miller Creek, into which the discharge of  
2 SDN1 flows. The above testing approach does not address chronic (longer-term) toxicity that  
3 could occur at much lower concentrations of stormwater.  
4

5 23. The Port wants us to believe that “the quality of stormwater from STIA will  
6 improve in the future for several reasons. First, areas where stormwater is currently not treated  
7 will be retrofitted to improve water quality. Second, for areas with new impervious surfaces,  
8 stormwater will be detained and treated.”

9 24. These statements suggest that the five or six major stormwater outfalls (SDN1,  
10 SDN2, SDN4, SDE4, SDS1, and SDS3) that now discharge to Miller and Des Moines Creeks  
11 will be retrofitted to improve water quality, yet this is not what is indicated in the *Comprehensive*  
12 *Stormwater Management Plan* (Parametrix 2000c). Section 7.1.5 indicates that a final decision  
13 to retrofit certain stormwater basins with additional detention, e.g., wet vaults or detention vaults,  
14 has not been made and that evaluation of the need continues. This affects both the SDE4 and  
15 SDS3 drainage basins, which outfall to Des Moines Creek at the south end of STIA. The reason  
16 for the delay is the cost in providing (constructing) additional detention.  
17  
18

19 25. Of the stormwater basins that discharge to Miller Creek at the north end of the  
20 STIA, only SDN1 could be retrofitted with additional detention capabilities but this too is subject  
21 to change. The Port in Section 7.1.4.1 indicates that they could also approve another alternative  
22 to improve treatment, although this alternative is yet to be determined. And, according to Table  
23  
24

AR 021421

1 7-8, the SDN2 and SDN4 will not receive a retrofit as the presently employed best management  
2 practices, e.g., bioswales, filter strips, are believed to be effective.

3 26. According to the *Comprehensive Stormwater Monitoring Plan*, all of the SDS1  
4 basin drainage was transferred to the IWS, although there still is a discharge from this basin that  
5 likely includes a contribution from STIA. For example, as recently as February 2001,  
6 stormwater from SDS1 still contained a total glycols concentration of 48 mg/L, which was  
7 mostly (43 mg/L) propylene glycol (Port 2001).  
8

9 27. So I must ask, what really will change? Will stormwater quality at the existing six  
10 outfalls likely improve with the proposed construction at STIA? The Port's proposed retrofit will  
11 not, in my opinion, improve the existing situation. The Port's assertion that "stormwater quality  
12 will improve in the future," is also misleading and without scientific basis.  
13

14 28. To provide a site for the Third Runway, the Port proposes to fill a ravine west of  
15 the airport with twenty (20) million cubic yards of fill. The fill would be stabilized in part by a  
16 retaining wall, fifteen stories high and close to fifteen hundred feet long. Underneath the 20  
17 million cubic yards of fill, the Port proposes to construct an enormous rock drain field to  
18 "capture" groundwater and transport it down slope in the hope of supporting the streams and  
19 wetlands below. Chemicals associated with fill materials at the fill placement site at STIA have  
20 the potential to percolate through the fill pile to groundwater, contaminating wetlands and  
21 surface waters. The Soil Acceptance Criteria contained in the Section 401 certification are  
22 seriously flawed and do not preclude the acceptance of chemically contaminated fill for use at the  
23  
24

25

1 third runway site. Already, there is evidence that fill, e.g., Hamm Creek Restoration Project  
2 sediments, already stockpiled at STIA, contains residual chemicals (PCBs, and DDTs).  
3  
4 Chemicals in fill would also have the potential to directly contaminate wetlands and surface  
5 waters through runoff following seasonal rains.

6 29. The Section 401 certification uses the State's Model Toxic Control Act (MTCA)  
7 to set the standard for acceptable fill for the third runway project. The fundamental purpose of  
8 MTCA is to cleanup existing contaminated or hazardous waste sites. MTCA sets reasonable  
9 standards for the amount of toxic material that can be left in a contaminated site. MTCA does  
10 not purport to clean-up to natural or background conditions. Instead, MTCA recognizes that  
11 there is a certain level below which it is not practical or feasible to clean. These standards are  
12 not, nor have they ever been, meant to contaminate clean property up to some predetermined  
13 level. To the best of my knowledge, the STIA property where the fill is being placed was free of  
14 contamination prior to any fill placement. It is my professional opinion that MTCA does not  
15 apply and should not be used for the purpose of screening soils or sediments for use on the STIA  
16 Third Runway Fill Project. It is an inappropriate standard for determining the quality of fill  
17 material to be placed in the area of wetlands and streams that are now in relatively pristine  
18 condition and which contain significant aquatic life.

19 30. The Section 401 certification Soil Fill Acceptance Criteria are supposed to  
20 preclude chemical contamination. However, they are fundamentally flawed in their lack of a  
21 consistent and statistically meaningful approach to determine the location and extent of any

1 contamination contained in candidate fill materials. Statistically rigorous sampling approaches  
2 exist, e.g., systematic grid system (Gilbert 1982), over sampling and compositing (Skalski and  
3 Thomas 1984) and are used routinely to survey sites for buried waste, yet no such approach is  
4 adopted in the 401 certification Soil Fill Acceptance Criteria. While such an approach need not  
5 be undertaken at State-certified borrow pits, they should be required at all sites like the First  
6 Avenue Bridge and Hamm Creek where contamination is known to occur.

8 31. In the past year, I have repeatedly advised the Ecology, the Army Corps of  
9 Engineers and the USEPA of my serious concerns about the inappropriate use of MTCA as a fill  
10 acceptance criteria for the third runway site. Attached hereto are true and correct copies of my  
11 letters to the agencies on this topic: Ex. D, August 31, 2000 letter to Tom Luster, Washington  
12 Department of Ecology; Ex. E, December 19, 2000 letter to Charles Findley, U.S. Environmental  
13 Protection Agency; and Ex. F, February 16, 2001 Comment letter to DOE and the Army Corps of  
14 Engineers.

16 32. There are also problems with the Port's Low Stream Flow Analyses (see  
17 Comprehensive Stormwater Management Plan [Parametrix 2000a]) in that the predictions may  
18 underestimate summer low flow impacts and overestimate the contributions of proposed  
19 mitigation and natural mitigating factors. For example, one option that the Port proposed in  
20 mitigation of predicted low stream flows is the use of "additional storage volume in the base of  
21 selected detention facilities, that can be used to store winter (wet) season runoff until needed to  
22 support low flows in the summer (dry) season." According to Mr. William Rozeboom of  
23

AR 021424

1 Northwest Hydraulic Consultants, Seattle, Washington (also working on behalf of ACC and  
2 submitting comments), some of the proposed detention facilities that are to be used in this way  
3 do not have "dead storage" capacity for reserve storm water release, with the result the total  
4 proposed storage falls short of the target volumes. Mr. Rozeboom also points out that the  
5 potential mitigating effect of the "fill infiltration discharge" from the proposed runway  
6 embankment to Miller Creek is overestimated, and that the "IWS lagoon lining improvements"  
7 would specifically reduce recharge for Walker and Des Moines Creeks. For these reasons and  
8 others (see the full text of Mr. Rozeboom's comments, attached to his declaration in support of  
9 ACC's request for stay), the Port's conclusion indicating that base lows will not be diminished  
10 beyond the values presented in Table 5 (page 18) of the Biological Assessment – Supplement  
11 (Parametrix 2000) is in serious doubt. Clearly, flow reductions have not been established with  
12 any degree of certainty.

15 33. From a fish or fish habitat perspective, it is my opinion, that if flows in the project  
16 streams fall much below 1.0 cfs, impacts to anadromous as well as resident fish species will  
17 likely occur, and over most of the length of the streams on the project site. If flows diminish,  
18 depths will surely decrease resulting in elevated temperatures and lower dissolved oxygen  
19 concentrations. Fish and other mobile aquatic life could be displaced to other reaches of the  
20 stream where preferred conditions persist. Diminished flow and depth could also limit  
21 movement of fish throughout the stream length and conceivable lead to stranding and mortality  
22 of larger fish.

1           34.     Finally, the Port's Low Flow Analysis/Flow Impact Offset Facility Proposal is  
2 incomplete and denies opportunity for meaningful scientific comment. The Port's management  
3 approach is to monitor the quality of detained or discharged stormwater, and only when a  
4 problem is encountered, will it take steps to mitigate the impacts of altered water quality. For  
5 example, if the problem is low dissolved oxygen, the Port will aerate. How the waters in the  
6 proposed detention vaults or the stream will be aerated, we aren't told except in a very general  
7 way. While several types of aeration devices are listed on page 18 , including microbubble  
8 diffusers, gas injection, mechanical aerators, etc., there is no commitment at this time to any of  
9 these technologies. It may be expected that one or more of these devices will work better than  
10 others but this has not been determined. This plan is not ready for scientific scrutiny.

11  
12  
13           35.     There is also the important issue of how frequently to monitor the stored  
14 stormwater during discharge. For example in the case of dissolved oxygen, the Port proposes a  
15 weekly monitoring requirement for the operational period, August through October which may  
16 not detect early signs of degradation. Dissolved oxygen, can change very quickly (in a matter of  
17 hours) in response to biochemical oxygen demand, rainfall, and even air temperature. I therefore  
18 cannot agree with the Port's assertion that "water quality of stored water is not expected to  
19 change." More frequent monitoring, at least daily for dissolved oxygen, turbidity, and  
20 temperature during the operational (discharge) period is necessary to assure that degradation does  
21 not occur. Modeling and bench-scale testing should have been required of the Port to determine  
22 how long-term (three month) detention can change the basic properties of stormwater.  
23

1           36.     While it may be of interest to undertake a long-term assessment (10 years) of  
2 benthic insect productivity in the project streams (see page 34), as demonstrated by the Benthic  
3 Index of Biotic Integrity (BIBI), this kind of biological monitoring also will not detect potential  
4 early impacts associated with the discharge of detained stormwater to the project streams. In  
5 other words, harm to the resource could occur before it was detected. There is also no real BIBI  
6 baseline for the project streams because so few samples have been collected to date from which  
7 the BIBI can be calculated. Using this approach, one will also have to wait several years to see a  
8 trend in the data that had sufficient statistical reliability to determine if benthic invertebrate  
9 productivity was being altered. In my opinion, then, it's a stretch to suggest as the Port does on  
10 page 34, "this monitoring will be able to be used in assessing any biological effects of the flow  
11 offset facility in the receiving water." Instead of the BIBI, use of either laboratory or *in situ*  
12 bioassays aimed at determining potential bioaccumulation and toxicity of metals and other  
13 chemicals is one approach that would provide more timely indications of whether or not stored  
14 stormwater was having an impact on the receiving water.  
15

16  
17           37.     The monitoring requirements contained in the Section 401 Certification should  
18 not be the basis for approving the low flow mitigation plan. If monitoring detects a problem it  
19 usually means that the stream(s) has/have suffered some degree of harm. More importantly, the  
20 streams will continue to undergo harm until the problem(s) is /are rectified. If the monitoring is  
21 flawed as the Port's monitoring appears to be, the degree of harm incurred could be all that more.  
22 Reasonable assurance that the water quality will not be impaired, in my opinion, should not be  
23

1 based on monitoring alone. Rather, it should be based on a facility design that is well grounded  
2 on scientific principles, a learned assessment of the potential problems, laboratory  
3 experimentation (not experimentation on the streams), and external peer review. See also my  
4 comment letters to Ecology and the Corps dated June 20, 2001 (Exhibit G), and August 6, 2001  
5 (Exhibit H).
